Abstract. In this first part we reinterpret the by now classical result of Spaltenstein or Bökstedt and Neeman of the construction of injective resolutions for unbounded chain complexes. Our point of view is that one can do homotopical algebra with unbounded complexes without knowing that they support a model category structure. There is an elementary model category of towers of bounded chain complexes which forms a model approximation for unbounded chain complexes. It encodes in particular all the homotopical information needed for example to construct resolutions.

INTRODUCTION

The construction of injective resolutions for bounded chain complexes is very classical, but it is only in the late eighties that Spaltenstein gave a first construction for unbounded chain complexes, [10]. A more conceptual interpretation for basically the same construction was then given five years later by Bökstedt and Neeman by studying homotopy limits in derived categories, [2]. It is also known that the category of unbounded chain complexes forms a Quillen model category (there is a proof of this fact for projective resolutions in Hovey’s book [8]), but our point of view is that often the existence of a model structure does not help so much to construct explicit resolutions, which is what the approaches of Spaltenstein and Bökstedt–Neeman provide.

Therefore we prefer to interpret the concrete description of the injective resolutions by saying that the category of unbounded chain complexes admits a model approximation by towers of bounded chain complexes. The concept of a model approximation has been introduced in [4] in order to construct homotopy limits and colimits in arbitrary model category. It provides a great deal of flexibility at the time of computing derived functors and the structure of the approximation encodes the way the resolutions are constructed. In the present situation we “approximate” an unbounded chain complex by successive truncations, which form a “tower” of bounded chain complexes. Since bounded chain complexes are easy to resolve, this category forms a model category. The algorithm to obtain a resolution for the original unbounded complex is now encoded in a pair of adjoint functors which is the heart of our main result Theorem 3.9 and reads as follows: Form first the

tower of truncations, then construct a fibrant replacement, a.k.a. injective resolutions, in the category of towers, and finally go back to unbounded chain complexes by taking the limit. This should sound familiar to anyone who has had a look at [10] or [2].

At the same time as we emphasize the explicitness of the construction, let us also say that the model approximation gives more than that. It yields in fact all the benefits of a model structure, such as the construction of the homotopy category in which the homotopy classes of maps form a set, and of course the possibility to compute derived functors. It is in this spirit that Quillen [9] developed his axiomatic homotopy theory.

In the sequel [3] of this first part our objective will be to relativize, i.e. to alter the choice of injective objects. The idea to alter the choice of projective or injective objects, and hence to do “relative” homological algebra is not new. The idea goes back at least to Adamson [1] for group cohomology and Chevalley-Eilenberg [5] for Lie algebra homology, these where subsumed in a general theory by Hochschild, [7]. The most complete reference for the classical point of view is Eilenberg–Moore, [6]. We will see how far our point of view can be pushed and will thus try to do relative homological algebra for unbounded chain complexes by constructing a suitable model approximation.

Acknowledgments. The third author would like to thank the Mathematics department at the Universitat Autònoma de Barcelona and Amnon Neeman at the Australian National University for providing terrific conditions for a sabbatical. We would like to also thank the generous support of the Göran Gustafssons Stiftelse.

1. Model approximations

In the next two sections we discuss our set-up for doing homotopical algebra. We explain how to localize certain categories and construct derived functors. In homotopy theory a convenient framework for doing this is given by Quillen’s model categories. We use the term model category as defined in Hovey’s book [8] or [4, Section 2]. There are however situations in which either it is very hard to construct a model structure or such a structure might not exist. The aim of this section is to explain how to construct right derived functors in a more general context than model categories. The idea is not to try to impose a model structure on a given category directly but rather use model categories to approximate a given category.

Let $\mathcal{C}$ be a category and $\mathcal{W}$ be a collection of morphisms in $\mathcal{C}$ which contains all isomorphisms and satisfies the “2 out of 3” property: if $f$ and $g$ are composable morphisms in $\mathcal{C}$ and 2 out of $\{f, g, gf\}$ belong to $\mathcal{W}$ then so does the third. We call elements of $\mathcal{W}$ weak equivalences and a pair $(\mathcal{C}, \mathcal{W})$ a category with weak equivalences. The concept of model approximation was introduced in [4].
Definition 1.1. A right Quillen pair for \((\mathcal{C}, W)\) is a model category \(\mathcal{M}\) and a pair of functors \(l : \mathcal{C} \rightleftarrows \mathcal{M} : r\) satisfying the following conditions:

1. \(l\) is left adjoint to \(r\);
2. if \(f\) is a weak equivalence in \(\mathcal{C}\), then \(lf\) is a weak equivalence in \(\mathcal{M}\);
3. if \(f\) is a weak equivalence between fibrant objects in \(\mathcal{M}\), then \(rf\) is a weak equivalence in \(\mathcal{C}\);

We say that this Quillen pair forms a right model approximation if moreover the following condition is satisfied:

4. for any weak equivalence \(lA \to X\) in \(\mathcal{M}\) with \(X\) fibrant, the adjoint \(A \to rX\) is a weak equivalence in \(\mathcal{C}\).

Note that if the condition (4) of the Definition 1.1 is satisfied for one fibrant replacement \(X\), then it is satisfied for all such fibrant \(X\).

Let us fix a right Quillen pair \(l : \mathcal{C} \rightleftarrows \mathcal{M} : r\). We recall now the key properties of model approximations, [4, Section 5]:

Proposition 1.2. (1) The localization \(\text{Ho}(\mathcal{C})\) of \(\mathcal{C}\) with respect to weak equivalences exists and can be constructed as follows: objects of \(\text{Ho}(\mathcal{C})\) are the same as objects of \(\mathcal{C}\) and \(\text{mor}_{\text{Ho}(\mathcal{C})}(X,Y) = \text{mor}_{\text{Ho}(\mathcal{M})}(lX,lY)\).

2. A morphism in \(\mathcal{C}\) is a weak equivalence if and only if it induces an isomorphism in \(\text{Ho}(\mathcal{C})\).

3. The class of weak equivalences in \(\mathcal{C}\) is closed under retracts.

4. Let \(F : \mathcal{C} \to \mathcal{T}\) be a functor. Assume that the composition \(Fr : \mathcal{M} \to \mathcal{T}\) takes weak equivalences between fibrant objects in \(\mathcal{M}\) to isomorphisms in \(\mathcal{T}\). Then the right derived functor of the restriction \(F : \mathcal{C} \to \mathcal{T}\) exists and is given by \(A \mapsto F(rX)\), where \(X\) is a fibrant replacement of \(lA\) in \(\mathcal{M}\).

For a given category with weak equivalences \((\mathcal{C}, W)\) our strategy is to construct a right model approximation \(l : \mathcal{C} \rightleftarrows \mathcal{M} : r\). We can then use it to localize \(\mathcal{C}\) with respect to weak equivalences and construct right derived functors as explained in Proposition 1.2. For this strategy to work we need examples of model categories. This is the purpose of the next section in which we show how to glue model categories together to build new ones.

2. Towers

For our purposes the most important example of a model category is constructed as towers of well known and simple model categories, very much in the same way as spectra can be seen as “telescopes of spaces” in a dual setting.

A tower \(\mathcal{T}\) of model categories consists of a sequence of model categories \(\{\mathcal{T}_n\}_{n \geq 0}\) and a sequence of Quillen functors \(\{l : \mathcal{T}_{n+1} \rightleftarrows \mathcal{T}_n : r\}_{n \geq 0}\) (for any \(n\), \(l\) is left adjoint to \(r\) and \(r\) preserves fibrations and acyclic fibrations). A tower of model categories can be assembled to form a category of towers:
Definition 2.1. Let $\mathcal{T}$ be a tower of model categories $\mathcal{T}_n$, with $n \geq 0$. The objects of the category of towers $\text{Tow}(\mathcal{T})$ are sequences $\{a_n\}_{n \geq 0}$ of objects $a_n \in \mathcal{T}_n$ together with a sequence of morphisms $\{a_{n+1} \rightarrow r(a_n)\}_{n \geq 0}$. We write $a_\ast$ to denote the object $\{a_n\}_{n \geq 0}$ in $\text{Tow}(\mathcal{T})$ and call the morphisms $\{a_{n+1} \rightarrow r(a_n)\}_{n \geq 0}$ the structure morphisms of $a_\ast$. The set of morphisms in $\text{Tow}(\mathcal{T})$ between $a_\ast$ and $b_\ast$ consists of sequences of morphisms $\{f_n : a_n \rightarrow b_n\}_{n \geq 0}$ for which the following squares commute:

\[
\begin{array}{ccc}
  a_{n+1} & \rightarrow & r(a_n) \\
  f_{n+1} & \downarrow & \downarrow r(f_n) \\
  b_{n+1} & \rightarrow & r(b_n)
\end{array}
\]

We write $f_\ast : a_\ast \rightarrow b_\ast$ to denote the morphism $\{f_n : a_n \rightarrow b_n\}_{n \geq 0}$ in $\text{Tow}(\mathcal{T})$.

For a morphism $f_\ast : a_\ast \rightarrow b_\ast$ in $\text{Tow}(\mathcal{T})$, define $p_0 := b_0$ and, for $n > 0$, define:

\[
p_n := \lim(b_n \rightarrow r(b_{n-1}) \xleftarrow{r(f_{n-1})} r(a_{n-1}))
\]

Set $\alpha_0 : a_0 \rightarrow p_0$ to be given by $f_0$ and $\beta_0 : p_0 \rightarrow b_0$ to be the identity. For $n > 0$, let $\alpha_n : a_n \rightarrow p_n$ be the projection from the inverse limit onto the component $b_n$, $\beta_n : p_n \rightarrow r(a_{n-1})$ be the projection from the inverse limit onto the component $r(a_{n-1})$, and $\alpha_n : a_n \rightarrow p_n$ be the unique morphism for which the following diagram commutes:

\[
\begin{array}{ccc}
  a_n & \xrightarrow{f_n} & \quad p_n \xrightarrow{\pi_n} \quad r(a_{n-1}) \\
  \downarrow{\beta_n} & & \downarrow{r(f_{n-1})} \\
  b_n & \quad \xrightarrow{r(a_{n-1})} \quad b_{n-1}
\end{array}
\]

The sequence $\{p_n\}_{n \geq 0}$ together with the morphisms $\{p_{n+1} \xrightarrow{\pi_n} r(a_n) \xleftarrow{r(\alpha_n)} r(p_n)\}_{n \geq k}$ defines an object $p_\ast$ in $\text{Tow}(\mathcal{T})$. Moreover $\{\alpha_n : a_n \rightarrow p_n\}_{n \geq 0}$ and $\{\beta_n : p_n \rightarrow b_n\}_{n \geq 0}$ define morphisms $\alpha_\ast : a_\ast \rightarrow p_\ast$ and $\beta_\ast : p_\ast \rightarrow b_\ast$ whose composition is $f_\ast$. For example, let $\ast_\ast$ be given by the sequence consisting of the terminal objects $\{\ast\}_{n \geq 0}$ in $\mathcal{T}_n$ and $f_\ast : a_\ast \rightarrow \ast_\ast$ be the unique morphism in $\text{Tow}(\mathcal{T})$. Then $p_0 = \ast$, and, for $n > 0$, $p_n = r(a_{n-1})$. The morphism $\alpha_n : a_n \rightarrow p_n = r(a_{n-1})$ is given by the structure morphism of $a_\ast$.

Definition 2.2. A morphism $\{f_n : a_n \rightarrow b_n\}_{n \geq 0}$ in $\text{Tow}(\mathcal{T})$ is called a weak equivalence (respectively a cofibration) if for any $n$, $f_n$ is a weak equivalence (respectively a cofibration) in $\mathcal{T}_n$. This morphism is called a fibration if, for any $n \geq 0$, $\alpha_n : a_n \rightarrow p_n$ is a fibration in $\mathcal{T}_n$.

For example the morphism $a_\ast \rightarrow \ast_\ast$ is a fibration if and only if $a_0$ is fibrant in $\mathcal{T}_0$ and, for $n > 0$, the structure morphism $a_n \rightarrow r(a_{n-1})$ is a fibration in $\mathcal{T}_n$. 
Proposition 2.3. **The above choice of weak equivalences, cofibrations, and fibrations defines a model category structure on** $\text{Tow} (\mathcal{T})$.

**Proof.** We start by observing first that the category $\text{Tow} (\mathcal{T})$ is bicomplete. The limits and colimits are formed “degreewise”. The structural morphisms of the limit are just the limits of the structural morphisms since the functors $r$, as right adjoints, commute with limits. For colimits, one considers the adjoints $l(a_{n+1}) \to b_n$ of the structural morphisms, takes the colimit $\text{colim}(a_{n+1}) \cong \text{colim}(l(a_{n+1})) \to \text{colim}(a_n)$, and its adjoint $\text{colim}(a_{n+1}) \to r(\text{colim}(a_n))$. These are precisely the structural morphisms of the colimit.

The 2 out of 3 property (MC2) for weak equivalences follows immediately from the same property in $\mathcal{T}_n$. That retracts of weak equivalences (resp. cofibrations) are weak equivalences (resp. cofibrations) again follows from the same property in $\mathcal{T}_n$. For fibrations, notice that if $\{c_n \to d_n\}_{n \geq 0}$ is a retract of a fibration $\{a_n \to b_n\}_{n \geq 0}$, then $c_0 \to d_0$ is a fibration in $\mathcal{T}_0$. Next consider the following commutative diagram for $n > 0$:

\[
\begin{array}{cccccc}
  d_n & \to & r(d_{n-1}) & \leftarrow & r(c_{n-1}) & \to & p'_n \\
  \downarrow & & \downarrow & & \downarrow & & \downarrow \\
  b_n & \to & r(b_{n-1}) & \leftarrow & r(a_{n-1}) & \to & p_n \\
  \downarrow & & \downarrow & & \downarrow & & \downarrow \\
  d_n & \to & r(d_{n-1}) & \leftarrow & r(c_{n-1}) & \to & p'_n \\
\end{array}
\]

By the retract property in $\mathcal{T}_n$ the morphism $c_n \to p'_n$ is fibration, for any $n \geq k$, and therefore so is $\{c_n \to d_n\}_{n \geq 0}$ in $\text{Tow}(\mathcal{T})$. This proves axiom (MC3).

Let us prove now the right and left lifting properties (MC4). Consider a commutative diagram:

\[
\begin{array}{ccc}
  a_\bullet & \to & c_\bullet \\
  \downarrow & \sim & \downarrow \\
  b_\bullet & \to & d_\bullet
\end{array}
\]

where the indicated arrows are respectively an acyclic cofibration and a fibration. In degree 0, a lift $b_0 \to c_0$ is provided by the model structure on $\mathcal{T}_0$. We construct the lift $b_\bullet \to c_\bullet$ inductively. Take the solved lifting problem at level $n$ and complete the picture with the structural maps to get...
the following commutative cube:

\[
\begin{array}{cccc}
  r(a_n) & \rightarrow & r(c_n) \\
  \downarrow & & \downarrow \\
  a_{n+1} & \rightarrow & e_{n+1} \\
  \downarrow & & \downarrow \\
  r(b_n) & \rightarrow & r(d_n) \\
  \downarrow & & \downarrow \\
  b_{n+1} & \rightarrow & d_{n+1}
\end{array}
\]

Denote as usual by \( p_{d+1} \) the pull-back of \( d_{n+1} \rightarrow r(d_n) \leftarrow r(c_n) \). By the universal property of the pull-back there is a morphism \( b_{n+1} \rightarrow p_{n+1} \) that makes the resulting diagram commutative. Since by definition \( c_{n+1} \rightarrow p_{n+1} \) is a fibration, the resulting lifting problem

\[
\begin{array}{cccc}
  a_{n+1} & \rightarrow & e_{n+1} \\
  \downarrow & & \downarrow \\
  b_{n+1} & \rightarrow & p_{n+1}
\end{array}
\]

has a solution and this is the desired morphism. The proof for the right lifting property for acyclic fibrations with respect to cofibrations is analogous.

We prove finally the factorization axiom (MC5). Consider a morphism \( a \rightarrow b \). The morphism \( a_0 \rightarrow b_0 \) can be factored as an acyclic cofibration followed by a fibration (respectively as a cofibration followed by an acyclic fibration) as (MC5) holds in \( T_0 \). We construct by induction on the degree a factorization \( a_{n+1} \leftarrow q_{n+1} \rightarrow b_{n+1} \). Consider the following commutative diagram:

\[
\begin{array}{cccc}
  a_{n+1} & \rightarrow & r(a_n) \\
  \downarrow & & \downarrow \\
  z_{n+1} & \rightarrow & r(q_n) \\
  \downarrow & & \downarrow \\
  b_{n+1} & \rightarrow & r(b_n)
\end{array}
\]

where the right column is obtained by applying the functor \( r \) to the factorization at level \( n \) and bottom right square is a pull-back. Since the functor \( r \) and cobase-change preserve (acyclic) fibrations, \( z_{n+1} \rightarrow b_{n+1} \) is an (acyclic) fibration if so is \( q_n \rightarrow b_n \). It is now enough to factor \( a_{n+1} \rightarrow z_{n+1} \) in \( T_{n+1} \) in the desired way to obtain the factorization of \( a_{n+1} \rightarrow b_{n+1} \).

**Example 2.4.** Let \( \mathcal{M} \) be a model category. The constant sequence \( \{ \mathcal{M} \}_{n \geq 0} \) together with the sequence of identity functors \( \{ \text{id} : \mathcal{M} \rightleftarrows \mathcal{M} : \text{id} \}_{n \geq 0} \) form a tower of model categories. Its category of towers can be identified with the category of functors \( \text{Fun}(\mathbf{N}, \mathcal{M}) \), where \( \mathbf{N} \) is the poset whose
objects are natural numbers, $N(n,l) = \emptyset$ if $n < l$, and $N(n,l)$ consists of one element if $n \geq l$. The model structure on $\text{Fun}(N,M)$, given by Proposition 2.3, coincides with the standard model structure on the functor category $\text{Fun}(N,M)$ (see [8]). For example, a functor $F$ in $\text{Fun}(N,M)$ is fibrant if the object $F(0)$ is fibrant in $M$ and for any $n > 0$, the morphism $F(n) \to F(n-1)$, induced by $n-1 < n$, is a fibration in $M$. A morphism $\alpha : F \to G$ is a cofibration in $\text{Fun}(N,M)$ if, for any $n \geq k$, $\alpha_n : F(n) \to G(n)$ is a cofibration in $M$.

3. AN APPROXIMATION FOR CLASSICAL HOMOLOGICAL ALGEBRA

We have now explained our set-up for doing homotopical algebra. In the rest of the paper we are going to illustrate how to use it to study unbounded chain complexes of modules over a commutative ring. We could as well do this in rather general abelian categories (satisfying the so-called axiom AB4*), but as soon as we come to the relative version which is the main subject of this article we will mainly focus on categories of modules anyway. The aim of this section is to provide a nice model category of towers which approximates the category of unbounded chain complexes. We are going to use the following notation:

3.1. We consider cohomological complexes (differentials raise the degree by one) in $R$-Mod, that is of the form $X = (\cdots \to X^i \xrightarrow{d^i} X^{i+1} \to \cdots)$. The category of such chain complexes is denoted by $\text{Ch}(R)$. We identify $R$-Mod with the full subcategory of $\text{Ch}(R)$ whose objects are chain complexes concentrated in degree 0.

For a chain complex $X \in \text{Ch}(R)$, the cocycles $\text{Ker}(d^i : X^i \to X^{i+1})$ are denoted by $Z^i(X)$, or simply by $Z^i$ and the coboundaries $\text{Im}(d^{i-1} : X^{i-1} \to X^i)$ are denoted by $B^i(X)$, or simply by $B^i$. The cohomology of $X$ is as usual $H^i(X) = Z^i(X)/B^i(X)$. A morphism of chain complexes $f : X \to Y$ is a quasi-isomorphism if $H^i(f) : H^i(X) \to H^i(Y)$ is an isomorphism for all $i \in \mathbb{Z}$. A chain complex is called acyclic if all its cohomology modules are trivial.

For an integer $n$, the symbol $\Sigma^n : \text{Ch}(R) \to \text{Ch}(R)$ denotes the shift functor that assigns to a complex $X$, the shifted complex given by $(\Sigma^n X)^i := X^{i-n}$ with the differentials given by $(-1)^n d^{i-n}$. Similarly for a morphism $f : X \to Y$ in $\text{Ch}(R)$, $(\Sigma^n f)^i := f^{i-n}$. For example, if $M$ is an $R$-module, then $\Sigma^n M$ denotes a chain complex where $(\Sigma^n M)^n = M$ and $(\Sigma^n M)^i = 0$ if $i \neq n$.

3.2. A morphism of chain complexes $f : X \to Y$ is a homotopy equivalence if there is a morphism $g : Y \to X$ such that $fg$ and $gf$ are homotopic to the identity morphisms. Homotopy equivalences are examples of quasi-isomorphisms.

A complex $X$ is called contractible if $X \to 0$ is a homotopy equivalence. For an $R$-module $M$ and an integer $k$, $D^k(M)$ denotes the chain complex where, for $i = k$ and $i = k + 1$, $D^k(M)^i = M$ and otherwise $D^k(M)^i = 0$, with the differential $d^k : D^k(M)^k \to D^k(M)^{k+1}$ given by $id_M$. Complexes of the form $D^k(M)$ are examples of contractible complexes.
3.3. Let $n$ be an integer. The full subcategory of $\text{Ch}(R)$ consisting of those chain complexes $X$ such that $X^i = 0$, for $i < n$, is denoted by $\text{Ch}(R)_{\geq n}$. The inclusion functor $\iota : \text{Ch}(R)_{\geq n} \to \text{Ch}(R)$ has both right and left adjoints. The left adjoint is denoted by $\tau_{\leq n} : \text{Ch}(R) \to \text{Ch}(R)_{\geq n}$ and is called truncation. This awkward notation comes from the fact that we will later on only truncate chain complexes in negative degrees.

Explicitly, $\tau_{\leq n}$ assigns to a complex $X$, the truncated complex:

$$\tau_{\leq n}(X) := (\coker(d^{n-1}) \xrightarrow{d^n} X^{n+1} \xrightarrow{d^{n+1}} X^{n+2} \xrightarrow{d^{n+2}} \cdots)$$

where in degree $n$, $\tau_{\leq n}(X)^n = \coker(d^{n-1})$, and for $i > n$, $\tau_{\leq n}(X)^i = X^i$. For a morphism $f : X \to Y$ in $\text{Ch}(R)$, $\tau_{\leq n}(f)^n$ is induced by $f^n$ and, for $i > n$, $\tau_{\leq n}(f)^i = f^i$.

For any $X \in \text{Ch}(R)$, the canonical morphism $X \to \tau_{\leq n}(X)$ is defined to be the morphism in $\text{Ch}(R)$ which is adjoint to the identity morphism $\iota : \tau_{\leq n}(X) \to \tau_{\leq n}(X)$ in $\text{Ch}(R)_{\geq n}$. Explicitly this morphism is given by the following commutative diagram:

$$\begin{array}{ccc}
X & \xrightarrow{(\cdots \xrightarrow{d^{n-2}} X^{n-1} \xrightarrow{d^{n-1}} X^n \xrightarrow{d^n} X^{n+1} \xrightarrow{d^{n+1}} \cdots)} & \tau_{\leq n}(X) \\
\downarrow & & \downarrow q \\
0 & \xrightarrow{\coker(d^{n-1}) \xrightarrow{d^n} X^{n+1} \xrightarrow{d^{n+1}} \cdots} & \coker(d^{n-1})
\end{array}$$

where $q$ denotes the quotient morphism.

Whereas unbounded complexes form a complicated category, bounded ones are easier to work with and it was already known to Quillen, [9] that they form a model category.

**Theorem 3.4.** The category of bounded chain complexes $\text{Ch}(R)_{\geq n}$ is equipped with a model category structure where weak equivalences are quasi-isomorphisms, cofibrations are degreewise monomorphisms in degrees $> n$, and fibrations are degreewise split epimorphisms with injective kernel. In particular $X$ is fibrant if $X^i$ is an injective module for all $i \geq n$.

As announced we are going to use the model categories $\text{Ch}(R)_{\geq n}$ to approximate the category $\text{Ch}(R)$ of unbounded chain complexes.

For $n \leq k$, the restriction of $\tau_{\leq k} : \text{Ch}(R) \to \text{Ch}(R)_{\geq k}$ to the subcategory $\text{Ch}(R)_{\geq n} \subset \text{Ch}(R)$ is denoted by the same symbol $\tau_{\leq k} : \text{Ch}(R)_{\geq n} \to \text{Ch}(R)_{\geq k}$. Note that this restriction is left adjoint to the inclusion $\iota : \text{Ch}(R)_{\geq k} \subset \text{Ch}(R)_{\geq n}$. Moreover the canonical morphism $X \to \tau_{\leq k}(X)$ can be expressed uniquely as the composition $X \to \tau_{\leq n}(X) \to \tau_{\leq k}(X)$, of the canonical morphism $X \to \tau_{\leq n}(X)$ for $X$ and $n$, and the canonical morphism $\tau_{\leq n}(X) \to \tau_{\leq k}(X) = \tau_{\leq k}(\tau_{\leq n}(X))$ for $\tau_{\leq n}(X)$ and $k$.

Consider now the sequence of model categories $\{\text{Ch}(R)_{\geq n}\}_{n \geq 0}$, with the model structures given by Theorem 3.4. The functor $\iota : \text{Ch}(R)_{\geq n} \subset \text{Ch}(R)_{\geq n-1}$ takes (acyclic) fibrations to (acyclic)
fibrations and hence the following is a sequence of Quillen functors:

\[ \{ \tau_n : \text{Ch}(R)^{\geq n-1} \rightleftharpoons \text{Ch}(R)^{\geq -n} : \text{in} \}_{n \geq 0} \]

We will use the symbol \( \text{Tow}(R) \) to denote the associated category of towers (see Section 2). Let \( X_{\bullet} \) be an object in \( \text{Tow}(R) \). We can think about this object as a tower of morphisms:

\[ \cdots \xrightarrow{t_3} X_2 \xrightarrow{t_2} X_1 \xrightarrow{t_1} X_0 \]

in \( \text{Ch}(R) \) given by the structure morphisms of \( X_{\bullet} \). Conversely, for any such tower where \( X_n \) is a chain complex that belongs to \( \text{Ch}(R)^{\geq -n} \), we can define an object \( X_{\bullet} \) in \( \text{Tow}(R) \) given by the sequence \( \{ X_n \}_{n \geq 0} \) with the morphisms \( \{ t_{n+1} \}_{n \geq 0} \) as its structure morphisms. In this way we can think about \( \text{Tow}(R) \) as a full subcategory of the functor category \( \text{Fun}(\mathbb{N}, \text{Ch}(R)) \) consisting of these functors \( X : \mathbb{N} \to \text{Ch}(R) \) for which \( X(n) \in \text{Ch}(R)^{\geq -n} \).

### 3.5
To be very explicit, \( \text{Tow}(R) \) is the category of the following commutative diagrams of \( R \)-modules:

\[
\begin{array}{cccccccc}
0 & \rightarrow & X_2^{-2} & \xrightarrow{d_2^{-2}} & X_1^{-1} & \xrightarrow{d_1^{-1}} & X_0 & \rightarrow & \cdots \\
\downarrow t_2^{-2} & & \downarrow t_2^{-1} & & \downarrow c_1 & & \downarrow d_1 & & \downarrow d_0 \\
0 & \rightarrow & X_1^{-1} & \xrightarrow{d_1^{-1}} & X_0 & \rightarrow & \cdots \\
\downarrow t_1^{-1} & & \downarrow c_0 & & \downarrow d_0 & & \downarrow d_0 & & \downarrow d_0 \\
0 & \rightarrow & X_0 & \rightarrow & \cdots
\end{array}
\]

where, for any \( n \geq 0 \) and \( i \geq -n \), \( d_{n+1} d_n = 0 \), i.e., horizontal lines are chain complexes.

We will always think about \( \text{Tow}(R) \) as a model category, with the model structure given by Proposition 2.3. For example, if we think about \( X_{\bullet} \) as a tower \( (\cdots \xrightarrow{t_3} X_2 \xrightarrow{t_2} X_1 \xrightarrow{t_1} X_0) \), then \( X_{\bullet} \) is fibrant if and only if \( X_0 \) is fibrant in \( \text{Ch}(R)^{\geq 0} \) and, for any \( n \geq 0 \), \( t_{n+1} : X_{n+1} \to X_n \) is a fibration in \( \text{Ch}(R)^{\geq -(n+1)} \). If we think about \( X_{\bullet} \) as a commutative diagram as above, then \( X_{\bullet} \) is fibrant if, for any \( i \geq 0 \), the \( R \)-modules \( X_0^i \) are injective, and, for any \( n > 0 \) and \( i \geq -n \), \( t_n^i \) has a section and its kernel is injective. Note also that since all objects in \( \text{Ch}(R)^{\geq -n} \) are cofibrant, then so are all objects in \( \text{Tow}(R) \).

Here is another way of describing the category \( \text{Tow}(R) \). Consider the constant sequence of model categories \( \{ \text{Ch}(R)^{\geq 0} \}_{n \geq 0} \) with the model structure given by Theorem 3.4 and the sequence of functors \( \{ \tau : \text{Ch}(R)^{\geq 0} \rightleftharpoons \text{Ch}(R)^{\geq 0} : \Sigma \}_{n \geq 0} \), where \( \Sigma \) is the shift functor defined in 3.1 that assigns to \( X = (X_0 \xrightarrow{d_0} X_1 \xrightarrow{d_1} \cdots) \) the shifted complex \( \Sigma X := (0 \xrightarrow{d_0} X^1 \xrightarrow{d_1} \cdots) \). The
functor $\tau = \Sigma^{-1} \tau_0$, see Point 3.3, is left adjoint to $\Sigma$. It is clear that $\Sigma$ takes (acyclic) fibrations in $\text{Ch}(R)^{\geq 0}$ into (acyclic) fibrations in $\text{Ch}(R)^{\geq 0}$. Let us denote this tower of model categories by $\mathcal{T}$.

Let $X_\bullet$ be an object in $\text{Tow}(\mathcal{T})$. The structure morphisms of $X_\bullet$ and the differentials of the chain complexes $X_i$ can be assembled to form a diagram similar to the one we have seen above, in which the horizontal lines are chain complexes. It then follows that $\text{Tow}(\mathcal{T})$ is isomorphic to $\text{Tow}(R)$.

Our aim is to approximate the category of unbounded chain complexes of $R$-modules by towers of bounded complexes. For this purpose we first need to construct a pair of adjoint functors $\text{tow} : \text{Ch}(R) \rightleftarrows \text{Tow}(R) : \text{lim}$.

**Definition 3.6.** Let $X$ be an object in $\text{Ch}(R)$. The **tower** $\text{tow}(X)$ is the object in $\text{Tow}(R)$ given by the sequence $\{\tau_n(X)\}_{n \geq 0}$ with the structural morphisms given by the the canonical morphisms $\{t_{n+1} : \tau_{n+1}(X) \to \tau_n(X)\}_{n \geq 0}$.

Explicitly, $\text{tow}(X)$ is represented by the following commutative diagram in $R$:

\[
\begin{array}{cccccccc}
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\tau_2(X) & 0 & \xrightarrow{\text{coker}(d^{-2})} & X^{-1} & \xrightarrow{d^{-1}} & X^0 & \xrightarrow{d^0} & X^1 & \xrightarrow{d^1} \cdots \\
\tau_1(X) & 0 & \xrightarrow{\text{coker}(d^{-2})} & X^{-1} & \xrightarrow{d^{-1}} & X^0 & \xrightarrow{d^0} & X^1 & \xrightarrow{d^1} \cdots \\
\tau_0(X) & 0 & \xrightarrow{\text{coker}(d^{-1})} & X^0 & \xrightarrow{d^0} & X^1 & \xrightarrow{d^1} & \cdots \\
\end{array}
\]

where $q$ denotes the obvious quotient morphisms. For a chain map $f : X \to Y$, the morphism $\text{tow}(f)$ is defined to be given by the sequence of morphisms $\{\tau_n(f)\}_{n \geq 0}$.

Recall that the category of towers $\text{Tow}(R)$ can be identified with a full subcategory of the functor category $\text{Fun}(\mathbb{N}, \text{Ch}(R))$.

**Definition 3.7.** The **limit** functor $\text{lim} : \text{Tow}(R) \to \text{Ch}(R)$ is the restriction of the standard limit functor $\text{lim} : \text{Fun}(\mathbb{N}, \text{Ch}(R)) \to \text{Ch}(R)$.

Explicitly, let $X_\bullet$ be an object in $\text{Tow}(R)$ given by a commutative diagram of $R$-modules as in Point 3.5. Then $\text{lim}(X_\bullet)$ is the chain complex obtained by taking the inverse limit in the vertical direction:

$$\text{lim}(X_\bullet)^i := \text{lim}(- \cdots \xrightarrow{t_2^i} X_2^i \xrightarrow{t_1^i} X_1^i \xrightarrow{t_0^i} X_0^i)$$

with the differential $d_i : \text{lim}(X_\bullet)^i \to \text{lim}(X_\bullet)^{i+1}$ given by $\text{lim}_n(d_n^i)$. On morphisms, the functor $\text{lim} : \text{Tow}(R) \to \text{Ch}(R)$ is defined in the analogous way by taking the inverse limits in the vertical direction.
Lemma 3.8. The functor \( \text{tow} : \text{Ch}(R) \to \text{Tow}(R) \) is left adjoint to \( \text{lim} : \text{Tow}(R) \to \text{Ch}(R) \).

Proof. Let \( Y \) be a chain complex in \( \text{Ch}(R) \) and \( X_\bullet \) be an object in \( \text{Tow}(R) \) given by the tower \[
\cdots \xrightarrow{t_3} X_2 \xrightarrow{t_2} X_1 \xrightarrow{t_1} X_0
\] of morphisms in \( \text{Ch}(R) \) with \( X_n \in \text{Ch}(R)_{\geq -n} \). Consider a morphism of chain complexes \( f : Y \to \lim(X_\bullet) \). Since \( \lim(X_\bullet) \) is the inverse limit of the tower \( X_\bullet \), the morphism \( f \) corresponds to a sequence of morphisms \( \{f_n : Y \to X_n\}_{n \geq 0} \) for which the following diagram commutes:

\[
\begin{array}{ccc}
  & Y & \xrightarrow{id} & Y & \xrightarrow{id} & Y \\
\cdots & \xrightarrow{t_3} X_2 & \xrightarrow{t_2} X_1 & \xrightarrow{t_1} X_0 & \xrightarrow{f_0} & \xrightarrow{f_1} & \xrightarrow{f_2} & Y \\
\end{array}
\]

Since the chain complex \( X_n \) belongs to \( \text{Ch}(R)_{\geq -n} \), the morphism \( f_n : Y \to X_n \) can be expressed in a unique way as a composition \( Y \to \tau_n(Y) \to X_n \) where \( Y \to \tau_n(Y) \) is the canonical morphism. The sequence \( \{\tau_n(Y) \to X_n\}_{n \geq 0} \) describes a morphism \( \text{tow}(Y) \to X_\bullet \) in \( \text{Tow}(R) \). It is straightforward to check that this procedure defines a natural bijection from the set of morphisms between \( Y \) and \( \lim(X_\bullet) \) in \( \text{Ch}(R) \) onto the set of morphisms between \( \text{tow}(Y) \) and \( X_\bullet \) in \( \text{Tow}(R) \).

The next proposition is the reinterpretation of the work of Spaltenstein [10] or Bökstedt and Neeman [2].

Theorem 3.9. The pair of functors \( \text{tow} : \text{Ch}(R) \leftrightarrows \text{Tow}(R) : \text{lim} \) is a right Quillen pair. It forms moreover a model approximation.

Proof. Properties (1), (2), and (3) are easy to verify, so that the pair of functors forms a Quillen pair. The content of the proposition is thus in property (4). It says that if \( I_\bullet \) is a fibrant replacement for the truncation tower \( \text{tow}(X) \) of some unbounded chain complex \( X \), then the canonical morphism \( X \to \lim(I_\bullet) \) is a quasi-isomorphism. This is basically a cohomological computation. Notice that the structure map \( I_{m+1} \to I_m \) induces an isomorphism \( H^i(X) \cong H^i(I_{m+1}) \to H^i(I_m) \) for \( i > n-m \).

This observation is [2, Application 2.4] and proves the claim.

Let us be very explicit about how one constructs then an injective resolution for an unbounded chain complex \( X \). First we construct its truncation tower \( \{\tau_n(X)\} \), then we form a fibrant replacement in the category of towers of bounded chain complexes. It can be obtained in a simple inductive process as follows. Construct an injective resolution \( I_0 \) for \( \tau_0 X \), and if \( I_n \) has been constructed choose \( I_{n+1} \) so that the structure map \( I_{n+1} \to I_n \) be a fibration, i.e. a degreewise split epimorphism with injective kernel. The tower \( I_\bullet \) is a special tower in Spaltenstein’s terminology. Its inverse limit is an unbounded chain complex of injective modules and the canonical map \( X \to \lim(I_\bullet) \) is a quasi-isomorphism as we have proven in the previous theorem.

This concludes this first part devoted to classical resolutions.
